Abstract—COVID-19, an infectious disease caused by the SARS-CoV-2 virus, was declared a pandemic by the World Health Organisation (WHO) in March 2020. At the time of writing, more than 2.8 million people have tested positive. Infections have been growing exponentially and tremendous efforts are being made to fight the disease. In this paper, we attempt to systematise ongoing data science activities in this area. As well as reviewing the rapidly growing body of recent research, we survey public datasets and repositories that can be used for further work to track COVID-19 spread and mitigation strategies. As part of this, we present a bibliometric analysis of the papers produced in this short span of time. Finally, building on these insights, we highlight common challenges and pitfalls observed across the surveyed works. We also created a live resource repository¹ that we intend to keep updated with the latest resources including new papers and datasets.

Index Terms—COVID-19, SARS-CoV-2, data science, artificial intelligence, machine learning, medical image analysis, text mining, speech analysis, bibliometric analysis

I. INTRODUCTION

The SARS-CoV-2 virus and the associated disease (designated as COVID-19) was first identified in Wuhan city (China) in December 2019 [¹]–[³], and was declared a pandemic by the World Health Organisation (WHO) on 11 March 2020. At the time of writing, the Centre for Systems Science and Engineering at Johns Hopkins University reported 2,790,986 confirmed cases, 195,920 deaths, and 781,382 recovered.

Since December 2019, over 24,000 research papers from peer-reviewed journals as well as sources like medRxiv are available online [⁴]. Understanding this rapidly moving research landscape is particularly challenging since much of this literature has not been vetted through a peer-review process yet. This paper tries to overcome this challenge by presenting a detailed overview and survey of data science research related to COVID-19. It is intended as a community resource to facilitate accessibility to the large volume of data and papers published in recent months. We use the term ‘data science’ as an umbrella term that encompasses all techniques that use scientific methods, algorithms, and systems to learn from structured and unstructured data. We recognise the importance of associated perspectives from the social sciences, ethics, history, and other humanities, but those areas are beyond the focus of this work.

In examining this growing landscape of data science research regarding COVID-19, we make the following five contributions. First, we present pressing research problems related to COVID-19, for which data scientists may be able to contribute. Second, we summarise publicly available COVID-19 datasets that are being used to drive research, and list how they could be utilised to address some of the aforementioned problems. Third, we survey some of the ongoing research in the area, highlighting the main topics covered. As our primary audience is computer scientists and engineers, we theme our discussion around the types of data analysis. Fourth, we broaden our analysis and present a bibliometric study of the rapidly growing literature on COVID-19. Fifth, bringing together our observations, we highlight some of the common challenges in this fast-moving space. We intentionally cast a wide net, covering research from several technical areas surrounding data science.

This paper builds upon recent reviews and perspective papers [⁵], [⁶] to help systematise existing resources and support the research community in building solutions to the COVID-19 pandemic. We have attempted in this review to be comprehensive and provide an up to date literature review, and highlight important applications, community resources,

publication trends, and challenges of data science research in COVID-19. However, in a rapidly-evolving field such as this, it is not possible for us to aim for exhaustiveness. Nonetheless we hope that our work will provide a very useful introduction to the field for researchers interested in this area.

The rest of this paper is organised as follows. In Section II, we present possible use cases where data science can help address COVID-19 challenges. In Section III, we present the details of available datasets and resources. In Section IV, we review contributions made by data scientists including image analysis, textual data mining, audio analysis, and embedded sensing. In Section V we present a bibliometric analysis of the COVID-19 related papers. Next, we discuss common challenges facing this research in Section VI. Finally, Section VII concludes the paper. The detailed organisation of the paper including details of the subsections can be seen in Table I.

II. APPLICATIONS OF DATA SCIENCE FOR COVID-19

Data science is a broad term covering topics such as Machine Learning (ML), statistical learning, time-series modelling, data visualisation, expert systems and probabilistic reasoning. In this section, we summarise some of the key research use cases to which data scientists may be able to contribute in countering COVID-19.

A. Risk Assessment and Patient Prioritisation

Healthcare systems around the world are facing unprecedented pressures on their resources (e.g., availability of intensive care beds, respirators). This creates the need to rapidly assess and manage patient risk, while allocating resources appropriately. In periods of peak load, this must be done rapidly and accurately, creating a substantial challenge for healthcare professionals who may not even have access to historical patient data. Various studies have already proposed algorithmic risk assessments of diseases such as cancer [7], diabetes [8], and cardiac-related diseases [9] with Artificial Neural Networks (ANNs). Due to diverse symptoms and disease trajectories, researching technologies for data-driven risk assessment and management in individual COVID-19 patients would be useful. For instance, traits like age, gender, or health state can be utilised to provide an estimate of mortality risk. This is particularly important when resources are limited, e.g., for patient prioritisation when Intensive Care Unit (ICU) resources are insufficient.

B. Screening and Diagnosis

A major issue facing countries with growing COVID-19 infection rates is the lack of proper screening and diagnosis facilities. This further complicates capacity management as well as social distancing measures, since those with mild symptoms are often unaware they carry the disease. A key use case is to develop remote computational diagnosis tools. Some already exist, which could be expanded, e.g., Babylon is a mobile app that provides medical advice via questioning. Other solutions could rely on valuable data from wearable or other monitoring devices, e.g. for audio, COVID-19 Sounds is a mobile app collecting audio of breathing symptoms to help perform diagnosis.\(^3\) We posit that such research will be particularly useful in developing countries that have a shortage of healthcare facilities [10]. Automated tools can also be developed to facilitate screening in larger groups of

\(^3\)http://www.covid-19-sounds.org/
people (e.g., at airports), e.g., using computer vision based thermal imaging to detect fever [11].

C. Simulation and Modelling

Currie et al. [12] provide a detailed review of how models and simulations can help reduce the impact of COVID-19. For example, accurate epidemiological models are indispensable for planning and decision making. Here we discuss some of the potential modelling and simulation use cases.

1) Epidemic Models: Epidemic models are used to predict the macroscopic behaviour of an infectious disease. A key use case is developing and parameterising such models. For example, in epidemiology, compartmental models are widely used [13]. In these models, populations are divided into compartments and the flow of people among compartments is modelled using (ordinary) differential equations. For example, COVID-19’s spread has recently been modelled using the SEIR model [14], [15], which models the flow of people between four states (or compartments): susceptible (S), exposed (E), infected (I), and recovered (R).

Generative models represent another broad class of models which proceed by generating consequences from causes (using hidden states and parameters). An example generative model is based upon ensemble or population dynamics that generate outcomes (new cases of COVID-19 over time) [15]. Such approaches can capture the effects of interventions (e.g., social distancing) and differences among populations (e.g., herd immunity) to predict what might happen in different circumstances in a single region [16]. Using (Bayesian) hierarchical modelling, one can combine several of these (epidemic) models to create a (pandemic) model of viral spread among regions [17]. For interested readers, websites offering COVID-19 forecasting have emerged⁵, each using a different model (although they should be treated with caution due to the uncertainty of such predictions [18] [19]).

Parameterising the above models requires up-to-date information on the virus spread. Thus, an important use case is finding ways to better capture such data. For instance, this could be done by processing social media information to identify people who are likely to have been infected, or even analysing ambulance call out data [20]. Another beneficial use case would be to develop ways to more accurately evaluate “what-if” scenarios with these models [18]. As an example, the initial policy of the UK government of adopting almost no social isolation measures was later changed based on results from an extended SEIR model from Imperial College London [21]. This model projected that without interventions there would be up to half a million fatalities, highlighting the importance of accurate predictions. A comprehensive review focused on modelling infectious disease dynamics in the complex landscape of global health can be seen at [22]. It is also worth mentioning that there are several national level modelling efforts underway in the UK, for e.g., The Royal Society is coordinating to bring together experts from several fields. They have established the Rapid Assistance in Modelling the Pandemic (RAMP)⁶ initiative which is focusing on mechanistic modelling of disease spread and outcomes and Data Evaluation and Learning for Viral Epidemic (DELVE)⁷ initiative which, on the other hand, is focusing on data-driven and inferential modelling of COVID-19.

2) Simulation Models: Simulation models have broad applicability and can be used in a variety of settings [12], including decisions that affect disease transmission—e.g., decisions related to quarantine and social distancing strategies; decisions regarding resource management—e.g., decisions related to capacity of in-patient hospital beds, critical care units, staffing, and resource allocation within and across regions; and decisions about care—e.g., deciding thresholds for admission and discharge of patients and minimising the impact on other patients. In particular, pandemics generate a large number of questions all of which cannot be answered by epidemiological models alone. A key use case is integrating a diversity of models into simulations that can be used to answer diverse questions. This might range from understanding disease spread to predicting the consumption of medical supplies for hospital management. By considering the range of model outputs, an additional benefit is that an estimate of uncertainty can be produced, which may help policy makers gauge expected benefits against risks. For interested readers, the review paper [12] provides an overview of the use of various simulation modelling methods—including those based on system dynamics [23], agent based models, discrete event simulations, and hybrid simulations—to reduce the impact of COVID-19.

D. Contact Tracing

Most countries reacted to the early stages of COVID-19 with containment measures. This typically involves rapidly identifying infected individuals, followed by quarantine and contact tracing. Countries, such as South Korea, conducted rigorous testing campaigns, which allowed other potentially infected contacts to be quickly quarantined. This approach has been seemingly successful in containing the outbreak [24]. A valuable use case can therefore be facilitating more rapid and comprehensive contact tracing at scale [25]. Smartphone contact sensing, online surveys and automated diagnosis have all been proposed to rapidly identify exposure [26]. For example, there are ongoing efforts to survey general populations via social media to learn of symptoms within individuals’ social networks [27]. Even prior to COVID-19, FluPhone [28] used Bluetooth communications to identify contacts between people, and BlueDot monitored outbreaks of infectious diseases to alert governments, hospitals, and businesses [29].

If data from contact tracing is augmented with personal information such as geolocation, health characteristics and test results (both for viral infection and post infection antibodies), there is the potential to update continually probabilistic estimates of the inferred states of individuals (never exposed, infectious, recovered and hence perhaps immune), the sensitivity and specificity of different types and makes of test, the

⁵For example: (1) COVID-19 worldwide peak forecasting method (https://www.people.vcu.edu/~tdinh/covid19/en/) and (2) COVID-19 forecasting (http://epidemicforecasting.org/)

⁷https://tinyurl.com/y99c33dc
patterns of disease progress for an individual and spatially for the population, how immunity declines over time and when and where significant new strains of COVID-19 emerge. While this information could be very helpful, the benefits will have to be weighed against concerns about loss of individual privacy (see Section VI-C).

E. Understanding Social Interventions

Governments have taken steps to manage social interactions as part of their response to COVID-19. We highlight two main use cases of relevance.

1) Monitoring of Social Distancing: Many governments have implemented social distancing strategies to mitigate the spread of COVID-19. This is a non-pharmaceutical intervention that reduces human contact within the population [30] and therefore constrains the spread of COVID-19 [31]. Data science can support contact tracing for the monitoring of social distancing, for instance by extracting social media data and using language processing techniques [32], [33]. These analyses could also help in keeping record of interactions to be used as individuals develop symptoms. Furthermore, these could be used for general population tracking to understand compliance with social distancing. This could then be complemented with other datasets (e.g., cellular trace data or air pollution monitoring [34]) to better understand human mobility patterns in the context of social distancing. Similar to the previous case, these solutions present complex trade offs with regards to privacy (see Section VI-C).

2) Controlling Misinformation & Online Harms: The spread of misinformation can undermine public health strategies [35] and has potentially dangerous consequences [36], [37]. For example, online rumours accusing 5G deployments of causing COVID-19 led to mobile phone masts being attacked in the UK [38]. Wikipedia maintains an up-to-date list of misinformation surrounding COVID-19 [39]. This confirms the spread of a number of dangerous forms of misinformation, e.g., that vinegar is more effective than hand sanitiser against COVID-19. Naturally, users who believe such misinformation could proceed to undermine public health. One important use case would therefore be to develop classifiers and techniques to stem this flow. For example, Pennycook et al. [40] are testing simple interventions to reduce the spread of COVID-19 misinformation. An infodemic observatory analysing digital responses in online social media to COVID-19 has been created by CoMuNe lab at Fondazione Bruno Kessler (FBK) institute in Italy, and is available online. The observatory uses Twitter data to quantify collective sentiment, social bot pollution, and news reliability and displays this visually.

F. Logistical Planning and Economic Interventions

COVID-19 has created serious challenges for healthcare supply chains and provisioning. This includes personal protective equipment such as masks and gowns, alongside intensive care equipment like test kits, beds, and ventilators. There is a history of applying machine learning to logistical planning, e.g., by Amazon Fulfilment. A simple use case would be to apply data science techniques to help supply chain management for healthcare provisioning. This can also be used to preemptively allocate resources, e.g., researchers from the University of Cambridge are using depersonalised data (like lab results and hospitalisation details) to predict the need for ventilation equipment. This use case could be critical for ensuring appropriate equipment is available on time.

Social distancing measures are also having a major impact on the global economy [41], [42]. As organisations emerge from economic hibernation they will be challenged to return to normal levels of service and operation given disruptions to their supply chains and workforce. Data scientists might be able to assist in identifying problems limiting recovery. For instance, governments can use data science techniques to identify optimal economic interventions at a high level of granularity and companies can use data science to detect unusual patterns of behaviour in the market or in their own customer base.

G. Automated Patient Care

The pandemic has triggered a shortage of healthcare workers (e.g., in primary care). To alleviate this, automated primary care tools, such as remote chatbots and expert systems, could be developed and/or improved. Such systems can help people in providing information about the outbreak, symptoms, precautionary measures, etc. For instance, an interactive chatbot by the WHO and Rakuten Viber aims to provide accurate information about COVID-19 to people in multiple languages.

Automated healthcare methods could also be utilised to help monitor the conditions of COVID-19 patients in emergency care [44]. Another use case would be to gather and collate observational data to monitor the efficacy of treatments for certain patient types, enabling decision support for better personalised patient treatment given limited resources. For example, the DeCOVID project at the Alan Turing Institute is attempting to use clinical data to identify factors and generate insights that can lead to more effective clinical strategies. Similarly, physical and psychological (self) recordings could be used to augment personal plans. Due to the need to rapidly discharge patients from hospitals, further monitoring could continue remotely. For instance, AliveCor [45] has launched Kardia Mobile 6L, which allows healthcare professionals to measure QTc (heart rate corrected interval). Similarly, TeleICU has been used to identify respiratory deterioration [46].

H. Supporting Vaccine Discovery and New Treatments

The international effort to discover or re-purpose drug treatments and vaccines can also benefit from extensive data science work predating COVID-19 [47]. For example, computational methods can reduce the time spent on examining data, predicting protein structures and genomes [48], [49]. It can
also assist in identifying eligible patients for clinical trials [50], an often costly and time consuming part of drug development. There is also substantial scope for applying advanced methods to managing trials, such as applying Bayesian clinical trials to adapt treatments based on information that accrues during the trial [51]. This may be critical in expediting the delivery of drug treatments, and we argue this is another area where data scientists can contribute.

III. DATASETS AND RESOURCES

To enable research by the community, it is vital that datasets are made available. Next, we survey public datasets, some of which we summarise in Table II.

A. COVID-19 Case Data

The number of COVID-19 cases along with their geo-locations can help to track the growth of the pandemic and the geographical distribution of patients. Many countries are collecting and sharing infection information. One of the most used datasets is collated by John Hopkins University, which contains the daily number of positive cases, the number of cured patients and the mortality rates at a country as well as state/province level [64]. A further source of daily COVID-19 case data is available at Kaggle [69]. This dataset is annotated with other attributes such as patient demographics, case reporting date and location. Another epidemiological dataset, nCOV2019 [68], contains national and municipal health reports of COVID-19 patients. The key attributes are geo-location, date of confirmation, symptoms, and travel history. Similarly, the New York Times is compiling a state-wise dataset consisting of the number of positive cases and death count [70]. Whereas the above datasets are mostly based on statistics compiled by governmental administrations, other datasets are being collated using community surveys, requesting people to report infection rates among their social networks [27]. Common data science applications used with such data in the literature include data visualisation and predictive analytics [74].

A key limitation in these datasets is the divergence of testing regimes, which makes it challenging to compare results across countries [75]. It is estimated in one study [11] that the average detection rate of SARS-CoV-2 infections is just 6% worldwide. Similarly, variations in interventions, population densities and demographics have a major impact, as can be seen when contrasting, for example, Japan vs. USA. [12] As such, regional prediction tasks are non-trivial, and we posit that temporal models such as Auto Regressive Integrated Moving Average (ARIMA) [76] and Long Short Term Memory (LSTM) [77] neural networks may be effective here.

B. COVID-19 Textual Data

The availability of rich textual data from various online sources can be used to understand the growth, nature and spread of COVID-19.

One prominent source is social media, for which datasets are already available covering COVID-19 discussions. There are open Twitter datasets covering Tweet IDs [71] and tweet text data [59]. These were gathered using Twitter’s Streaming API to record tweets containing a series of related keywords, including “Coronavirus”, “COVID-19”, “N95”, “Pandemic”, etc. Another dataset of 2.2 million tweets, alongside the code to collect more data is available [78]. This data could be used to monitor the spread of COVID-19, as well as people’s reactions (e.g., to social distancing measures) using existing natural language processing techniques [79]–[81]. Sharma et al. [82] also made a public dashboard available summarising data across more than 5 million real-time tweets. There are also textual datasets that include image content: Zarei et al. [83] provide 5.3K Instagram posts related to COVID-19, including 18.5K comments.

The wealth of academic publications in recent weeks is also creating a deluge of textual information. Information extraction from clinical studies is already being performed [84] using language processing models such as [85]. These bibliometric datasets can easily be collected from pre-print services such as arXiv, medRxiv, and biorXiv [86]–[88]. The White House has also released an open research articles dataset [57]. This dataset contains nearly 45,000 articles related to COVID-19, SAR-CoV-2 and other coronaviruses. These activities are mirrored across other organisations. For instance, in the US, The National Center for Biotechnology Information (NCBI) is providing up-to-date COVID-19 scientific literature [66], and WHO is compiling a database of recent research publications [62]. Closely related is the wealth of activity on Wikipedia, a community-driven encyclopedia, which already contains substantial information about COVID-19. The entirety of Wikipedia can be downloaded for offline analysis [89], and there are already pre-processed Wikipedia datasets focusing on COVID-19 available. [14]

C. COVID-19 Biomedical Data

Biomedical data can be used to support diagnosis, prognosis and treatment. A major source of data are physical medical reports (such as X-rays) or clinical pathology reports (genomic sequencing). As the current diagnosis and prognosis of COVID-19 often requires human interpretations, there is potential for applications of computer vision research, e.g., automated diagnosis from chest X-rays. Currently, there are some open-source COVID-19 X-ray scans such as the COVIDx dataset [90]. These can be used for training COVID-19 infection assessment and diagnosis models (exploiting known computer vision techniques [91]). Other X-ray datasets that are publicly available for research are [53], [92]. The latter contains date, patient, demographics, findings, location and survival information. However, there are some intrinsic challenges related to these X-ray datasets, such as the requirement of radiologists or clinicians for data labelling and annotation (before training models). As such, the datasets are still small,

limiting the application of methods like convolutional neural networks.

Lung Computed Tomography (CT) scans can also be used for COVID-19 diagnosis and prognosis. Currently, there are datasets of lungs CT scans available. One of the datasets [54] covers 60 patients and comprises three class labels: ground glass, consolidation, and pleural effusion. The dataset is collected from 6, March to 13 March, 2020. A larger dataset of 288 CT scans collected from 19 January to 25 March, 2020 [93]. The dataset has 275 CT scans of COVID-19 patients, which to the best of our knowledge, is the largest publicly available.

Besides the above physical scans, there are important genomic sequencing datasets available. The study of drug impact, protein-protein interactions and RNA structure in genomic data is an essential part of diagnosis test evaluations. Available datasets related to epidemiological and clinical data include RCSBdata [72] and GHDDI [94]. However, as COVID-19 has emerged very recently, these datasets are mostly incomplete or too small. For example, the biomedical datasets (see [93]) range from just a few up to 300 patients.

D. Other Supportive Datasets

As part of monitoring secondary factors related to COVID-19 and the surrounding interventions, there are several other relevant datasets. For example, air quality index statistics can be used as an indirect measure of social distancing polices, i.e., if movements are restricted there will be fewer vehicles (and pollution). For example, a recent study showed that the air quality of six populous world cities has improved between February and March 2020 due to the measures to combat COVID-19 [34]. The data is publicly available [95] as well as the related COVID-19 case data [64]. Mobility trace data [96] can also serve a similar purpose—a collection of such logs is available here [97]. Note that mobility datasets have already been re-purposed: Google has released community mobility reports for public health officials in 131 countries [55]. These reports are compiled using Google Maps and describe how busy places such as grocery stores, transit stations, and workplaces are.

E. COVID-19 Competition Datasets

To facilitate and promote research in this area, there are several recent open data science competitions established on Kaggle (summarised in Table III). These are mostly based on the previously discussed data. For instance, the White House in coalition with some leading research groups (e.g., Kaggle and SGS Digicomply) has opened a new challenge using the earlier mentioned dataset of 45,000 research articles [57]. For this, there a few questions posed; for example, “What do we know about virus genetics, origin, and evolution?” For each task, there is an associated prize of $1000.

TABLE III: COVID-19 Related Kaggle Competitions

<table>
<thead>
<tr>
<th>Challenges</th>
<th>Aims</th>
</tr>

<td>This challenge asks data scientists to use exploratory analysis to answer research questions that help support frontline responders.</td>
</tr>
</tbody>
</table>
The Roche Data Science Coalition (RDSC) also established the challenge “UNCOVER COVID-19” [98]. RDSC has rolled-out a multi-modal dataset collected from 20 sources and has posed questions prepared by front-line healthcare experts, medical staff, WHO and governmental policymakers. This dataset is mainly collected from John Hopkins, the WHO, New York Times and the World Bank. It includes local and national COVID-19 cases, geo-spatial data and social distancing polices. Participants are required to design solutions to address questions like “which populations are at risk of contracting COVID-19?” and “which populations have contracted COVID-19 and require ventilators?”

Finally, the White House Office of Science and Technology Policy (OSTP) has opened a weekly challenge to predict the number of COVID-19 cases and fatalities at particular locations around the world [99]. Competitors are also required to unveil the factors associated with COVID-19 transmission rate. At the time of writing, participants are required to forecast the number of COVID-19 cases and deaths between 1-April-20 to 07-May-20.

For those wishing to engage in these competitions, there are several helpful tools and guideline blogs available. These resources provide support for data preprocessing, visualisations, and the implementation of different frameworks. We provide a list in Table IV.

#### IV. Survey of Ongoing Data Science Related COVID-19 Research

The above provides an overview of publicly available datasets that could be used by researchers wishing to contribute to the COVID-19 crisis. Next, we detail some of the ongoing research in this space. We theme this section around the above datasets and summarise key studies in Table V.

### A. Image Data Analysis

Various studies [101]–[103] have used computer vision algorithms to speed up the process of disease detection across several imaging modalities with some studies demonstrating that image analysis techniques have the potential to outperform expert radiologists [104], [105]. To diagnose COVID-19, two medical imaging modalities (CT and X-ray) have been experimented with, which we discuss below.

1) **Computed Tomography (CT) Scans:** Recent studies have found that radiologists can diagnose COVID-19 using Chest CT scans with lower false positive rates [106], [107] than other imaging modalities such as X-ray and Ultrasound scans. Thus, many deep learning (DL) techniques related to CT scans have been proposed to expedite the diagnosis process. Wang et al. [108] utilise DL methods to detect radiographical changes in COVID-19 patients. They evaluate the proposed model on the CT scans of pathogen-confirmed COVID-19 cases and show that DL can extract radiological features suitable for COVID-19 diagnosis. Xiaowei et al. [109] present a method for the automatic screening of COVID-19 in pulmonary CT scans using a 3D DL model with location-attention. They achieve promising accuracy to identify COVID-19 infected patients scans from other well-known infections. Chen et al. [110] exploit the U-Net++ architecture [111] to detect suspicious lesions on CT scans. They trained their model on 289 scans and test on 600 scans. They achieve 100% accuracy in identifying the suspicious areas in CT scans of COVID-19 patients, which suggests their techniques have potential for clinical utilisation. Ophir et al. [112] employ 2D and 3D convolutional neural networks (CNNs) to calculate the Corona score (which represents the evolution of the disease in the lungs). They estimate the presence of the virus in each slice of CT scan with a 2D CNN and detect other lung diseases (i.e., lung nodule) by using a 3D CNN. Similarly in [113], a neural network (COVNet), is developed to extract visual features from volumetric chest CT exams for the detection of COVID-19. The study suggests that DL-based models can accurately detect COVID-19 and differentiate it from community acquired pneumonia and other lung diseases.

2) **X-ray Scans:** Ongoing image processing work is not limited to CT scans, and there has been work on other modalities, namely X-rays scans. Although less sensitive than CT scans, they are less invasive, have a lower ionising radiation dose, and are more portable. Following the IR(ME)R 17 guidelines, ionising radiation dose should be kept as Low As Reasonably Achievable (ALARA) whilst still producing an image of diagnostic quality. [114]. Ezz et al. [115] propose a DL-based framework (COVIDX-Net) to automatically diagnose COVID-19 in X-ray images. COVIDX-Net includes seven different CNN models, such as VGG19 [116] and Google MobileNet [117]. The models can classify the patient status as either COVID-19 negative or positive. However, due to a lack of data, the technique is validated on only 50 X-ray images, among which 25 were of confirmed corona patients. Linda et al. [90]
introduce another DL-based solution tailored for the detection of COVID-19 cases from chest X-ray images. They also develop a dataset named COVIDx and leverage it to train a deep CNN. In [118], three different CNN-based models (i.e., ResNet-50, Inception and InceptionResNet) are employed to detect COVID-19 in X-rays of pneumonia infected patients. The results show that the pre-trained ResNet-50 model [119] performs well, achieving 98% accuracy. Similarly, Farooq et al. [120] provide the steps to fine-tune a pre-trained ResNet-50 [119] architecture to improve model performance for detecting COVID-19 related abnormalities (called COVID-ResNet). Prabira et al. [121] use DL to extract the meaningful features from chest X-rays, and then trained a support vector machine (using the extracted features) to detect infected patients.

We also briefly note that several companies have released commercial solutions, some of which are freely available, e.g., Lunit [122] CXR solution for COVID-19 and VUNO Med [123] solution for chest CT and X-ray scans. Such solutions help to expedite the initial screening of COVID-19.

### B. Textual Data Analysis

Researchers are currently utilising text mining to explore different aspects of COVID-19, mainly from social media and bibliometric data. To assist in this, Kazemi et al. [154] have developed a toolbox for processing textual data related to COVID-19. This toolbox comprises English dictionaries related to the disease, virus, symptoms and protein/gene terms.

In terms of social media research, Lopez et al. [155] explore the discourse around the COVID-19 pandemic and government policies being implemented. They use Twitter data from different countries in multiple languages and identify the popular responses to the pandemic using text mining. Similarly, Saire and Navarro [156] use text mining on Twitter data to show the epidemiological impact of COVID-19 on press publications in Bogota, Colombia. Intuitively, they find that the number of tweets is positively correlated with the number of infected people in the city. Schild et al. [142] inspect Twitter and 4Chan data to measure how sinophobic behaviour, driven by the pandemic, has evolved. This includes studying the impact that real world events, such as regional containment measures, have on online hate. Cinelli et al. [157] analyse Twitter, Instagram, YouTube, Reddit and Gab data about COVID-19. They find different volumes of misinformation on each platform. Singh et al. [158] are also monitoring the flow of (mis)information flow across 2.7M tweets, and correlating it with infection rates to find that misinformation and myths are discussed, but at lower volume than other conversations. For those seeking easy access to this information, FBK institute is collecting COVID-19 related tweets to visualise the presence of bots and misinformation.15

In terms of bibliometric analysis, Li et al. [159] analyse research publications on other coronaviruses (e.g, SARS, MERS). This is used to build a network-based drug re-purposing platform to identify drugs for the treatment of COVID-2019. Using module detection and drug prioritisation algorithms, the authors identify 24 disease-related human pathways, five modules and suggest 78 drugs to re-purpose. The rapid growth in COVID-19 related literature further led Hossain et al. [160] to perform a bibliometric analysis of COVID-19 related studies published since the outbreak. They review relationships, citations and keywords, which could be useful to new researchers in the area.

Finally, there is work processing text data from patient records. Roquette et al. [161] train a deep neural network to forecast patient admission rates using the unstructured text data available for triage. There are also other studies that utilise text data mining techniques to explore the important aspect of current situation.

### C. Voice Sound Data Analysis

The most common symptoms of COVID-19 are linked to pneumonia, and the main mortality risk is cardiovascular disease followed by chronic respiratory disease. Hence, audio analysis has been considered a potential means for lightweight diagnosis. There is work performing diagnosis with respiratory and lung sound analysis [162], which can work even with low-cost smartphones [163]. High mortality risk groups, including the elderly, can also be continuously monitored using speech analysis [164]. The patterns of coughs [165], [166], sneezing [165], throat clearing and swallowing sounds [167] can all be analysed using speech and sound processing. At present, COVID-19 related speech data has limited availability, although the potential benefits are highlighted in [162]. Thus, mobile apps like COVID-19 Sounds are attempting to collect large audio datasets. In [168], the authors present an app called AI4COVID-19 for the preliminary diagnosis of COVID-19. It requires a 2 second cough sample and provides the preliminary diagnosis within a minute. This work confirms the feasibility of COVID-19 detection using cough samples with promising results (90% detection rate).

### D. Embedded Sensor Data Analysis

Embedded data (e.g., from smartphones and sensors) is being used for remote patient care and diagnosis [169]. This can include mobility data, physiological vital signs, blood glucose, body temperature, and various other movement-related signals. In [170], the authors develop a system utilising real-time information, including demographic data, mobility data, disease-related data, and user-generated information from social media. The proposed system, called α-Satellite, can provide hierarchical community-level risk assessment that can inform the development of strategies against the COVID-19 pandemic. Google has also been using location data from smartphones to show people’s movement during the pandemic [171]. Another study [172] presents the design of a low-cost framework for the detection of COVID-19 using smartphone sensors. They propose the use of the mobile phones of radiologists for virus detection. They highlight that the proposed framework is more reliable as it uses multi-readings from different sensing devices that can capture symptoms related to the disease.

Another recent study [25] concluded that COVID-19’s “spread is too fast to be contained by manual contact tracing”. To address this, disease tracking apps [28] use contact/location

---

</tbody>
</table>
sensor data. The simplest ones aim to understand the spread of the disease, particularly mild cases that are not routinely lab tested. For example, the COVID Symptom Tracker app\(^{16}\) and COVID Near You\(^{17}\) service. Others, like Hong Kong’s StayHomeSafe and Poland’s Home Quarantine app \(^{173}\), try to monitor if people obey quarantine rules (via geofencing). More advanced solutions can notify users if they have come into contact with somebody infected. Examples include China’s Close Contact Detector app \(^{174}\), China’s complementary QR health code system \(^{175}\), Singapore’s TraceTogether \(^{176}\) app, and Israel’s HaMagen \(^{177}\) app. The UK is also planning to launch a similar app \(^{178}\).

We note that one critical challenge in the above apps is protecting user privacy \(^{179}\), \(^{180}\). For instance, uploading contact data for server-side computation could create a nationwide database of social relationships, particularly in countries where usage is mandatory. To address this, Decentralised Privacy-Preserving Proximity Tracing (DP-3T) \(^{181}\) was proposed. This is a mobile app that offers privacy-preserving alerts for people who may recently been in contact with an infected person. TraceSecure \(^{182}\) supports similar features based on homomorphic encryption, whereas \(^{183}\) offers privacy guarantees via private set intersection. Apple and Google have announced a partnership to develop their own privacy-preserving contact tracing specifications based on Bluetooth.\(^{18}\)

### E. Pharmaceutical Research

There is extensive ongoing work in using new experimental technologies to support the search for COVID-19 pharmaceuticals. This has received substantial attention in recent months in an attempt to build models to explore the 3D structure of SARS-CoV-2 (the virus that causes COVID-19). In \(^{184}\), the authors use the AlphaFold model to predict the structures of six proteins related to SARS-CoV-2. AlphaFold \(^{185}\) is a DL model based on a dilated ResNet architecture \(^{119}\), which predicts the distance and the distribution of angles between amino acid residues on protein structure. In \(^{186}\), the authors use a DNN-based model for de novo design of new small molecules capable of inhibiting the chymotrypsin-like (3CL) protease—the protein targets for corona-viruses. Based on the results they were able to identify 31 potential compounds as ideal candidates for testing and synthesis against SARS-CoV-2. Studies also attempt to improve the RT-PCR test by using ML and novel genome technologies. Metsky et al. \(^{187}\) employ CRISPR\(^{19}\) to develop assay designs for the detection of 67 respiratory viruses including SARS-CoV-2.

As well as the above, studies have utilised ML models to speed up drug development. Hu et al. \(^{188}\) exploit a multi-task DNN for the prediction of potential inhibitors against SARS-CoV-2. They aim to identify existing drugs that can be re-purposed. Based on the results, they list 10 potential inhibitors for SARS-CoV-2. Zhang et al. \(^{189}\) perform DL-based drug screening against 4 chemical compound databases and tripeptides for SARS-CoV-2. Based on the results, they provide a list of potential inhibitors that can help facilitate drug development for COVID-19. Tang et al. \(^{190}\) propose the use of reinforcement learning (RL) models to predict potential lead compounds targeting SARS-CoV-2. Similarly, in \(^{191}\) the authors propose a collaborative and open antiviral discovery approach using deep RL technique to discover new molecules to fight COVID-19.

Finally, pharmaceutical interventions must go through clinical trials before being deployed. Accelerated clearance pathways for COVID-19 studies have been established by several regulators including the WHO, the European Medicines Agency, the UK Medicines and Healthcare products Regulatory Agency and the US Food and Drug Administration \(^{192}\). As of March 24, 2020, 536 relevant clinical trials were registered. A major barrier though is recruiting suitable patients. Data-driven solutions are available to rapidly identify eligible trial participants \(^{50}\), \(^{193}\), and data collection platforms already exist for monitoring symptoms remotely \(^{194}\).

### V. Bibliometric Analysis of COVID-19 Research

We next augment the survey in the previous section with a brief bibliometric analysis of the literature related to COVID-19. This gives a broader understanding of how publications have evolved across the short lifespan of the pandemic.

#### A. Bibliometric Data Collection

There are many data repositories which contain COVID-19 research articles, both peer-reviewed \(^{66}\), \(^{195}\), \(^{196}\) and non-peer reviewed \(^{86}\)–\(^{88}\). We use Scopus to crawl peer reviewed articles, and arXiv, medRxiv, and biorXiv for non-peer reviewed articles. Peer-reviewed articles in our dataset are from top venues, including Nature \(^{197}\), Science \(^{198}\), the Lancet \(^{199}\), and the British Medical Journal (BMJ) \(^{200}\). See Table VI for a complete list of peer-reviewed articles and the number of articles in our dataset of COVID-19 publications. We developed scripts to gather this data from pre-print archives and database queries to fetch data from the Scopus database. Each entry includes title, authors, journal, publication date, etc. Our dataset covers papers on COVID-19 from all of the mentioned sources till April 23, 2020. We extracted these papers from the corpus of papers using keyword matching on titles and abstract of the paper. We use “COVID-19”, “COVID”, “CoronaVirus”, “Corona Virus”, “Pandemic”, “Epidemic”, and “SARS-CoV-2” as candidate keywords. Finally we did a manual check to confirm that extracted papers do not include any unrelated papers. In total, the dataset covers 5755 publications, of which 2797 are pre-prints and 2958 are from peer reviewed journals.

#### B. Peer-reviewed vs. Non-peer-reviewed publications

The pandemic has resulted in the rapid production of academic material, much of which is yet to go through the peer review process due to the urgency of dissemination.
Figure 1 presents the cumulative number of COVID-19 related papers published since December, 2019 including non-peer-reviewed COVID-19 literature. We see that the number of papers has increased dramatically since the beginning of January. To date, non-peer-reviewed articles are the most numerous (bioRxiv, medRxiv and arXiv combined), whereas peer reviewed articles are also increasing equally. By far the most active outlet is medRxiv, which has published 61% of all non-peer reviewed papers in our dataset. Table VI presents the number of publications from each journal covered. We see a highly skewed distribution: the top five journals based on publication count i.e. The Lancet, Nature, the BMJ, Science and The JAMA contribute around 1/3 of peer-reviewed publications of our dataset. Of course, we anticipate this will change in the long-term, as more pre-prints move into peer reviewed journals.

Figure 2 complements the above analysis by presenting the geo-distribution of both groups of publications. As the initial epicentre of COVID-19 pandemic, a major part of COVID-19 research has been contributed by China. The USA holds the second position in terms of research contributions. China has 1378 peer reviewed article and 882 non peer reviewed articles on COVID-19 in our dataset.

C. Research Topics

We next use topic modelling to identify core sub-topics within the publications. For this, we use Latent Dirichlet Allocation (LDA) [201]. This algorithm extracts and clusters abstract topics that exist within the papers. We divide our dataset into two groups: (1) all papers, and (2) data science papers.
COVID-19 papers. These topics show that data science research on COVID-19 is being carried out using various techniques and algorithms. Noteworthy algorithms and techniques include multidimensional kernel estimation, Bayesian learning, and deep learning based epidemic forecasting with synthetic information (TDFESI). We hope that these results will be useful to the community in identifying key topics receiving coverage.

**D. COVID-19 vs. Earlier Epidemics**

We conclude our bibliometric analysis by briefly comparing the rate of publication for COVID-19 research vs. prior epidemics. For this, we select Ebola and SARS-CoV-1. Figure 3 presents a time series for the first 3 years of peer reviewed publications. Note that the X-range differs and, naturally, we only have data since December 2019 for COVID-19.

We see that COVID-19 literature is growing faster than any prior epidemic. There have been more peer-reviewed publications (~2.9K) in around 4 months for COVID-19 than there were in 3 years for SARS-COV-1 and Ebola. Furthermore, as noted in the earlier subsection, there are even more pre-prints being released which means that COVID-19 has rapidly overtaken other epidemics in terms of academic attention. Of course, this is driven in-part by the wider geographic coverage of COVID-19, impacting numerous highly research active countries (e.g., China, USA, UK, Germany).
TABLE VIII: Top topics discussed in COVID-19 data science based research papers

VI. CHALLENGES IN DATA SCIENCE RELATED COVID-19 RESEARCH

In this section, we highlight some of the most important data science challenges. We specifically focus on cross-cutting challenges that impact all of the previously discussed use cases.

A. Data Limitations

Data science systems typically learn and improve as more data is gathered over time. Ideally, the data should be of high fidelity and voluminous. For many of the above use cases, extensive labelled datasets are not yet available, e.g., for speech analysis. Although there are a few publicly available datasets for medical images and textual analysis, these datasets are small compared to the requirements of deep learning models. For example, in the case of biomedical data, sample sizes range from a few up to 60 patients (see [54]). The scarcity of measured data is frequently due to the distributed nature of many data sources. For example, electronic healthcare records are often segregated on a national, regional, or even per-hospital level. A key challenge is therefore federating these sources, and overcoming practical differences across each source, e.g., in terms of schemas. Thus, better and more automated approaches to data munging, data wrangling etc. may be critical in attaining fast, reliable and robust outcomes. Common standards and international collaboration will help.

Beyond these challenges regarding availability of data, there are also major challenges within the data itself. The time-critical nature of this research is causing hurdles in developing certain types of high-quality dataset. For instance, by the time social media data is collected, curated and annotated it can become out-of-date. Due to this, COVID-19 datasets and their causal interpretations often contain poorly quantified biases [75]. For example, daily infection rates in Japan exhibit few similarities to those in the Italy. Training models on unrepresentative datasets will lead to poor (and even dangerous) outcomes. Whereas techniques such as transfer learning could allow models to be specialised with regional characteristics, the fast-moving nature of the problem can make it difficult to perform informed model selection and parameterisation. A key challenge is devising analytical approaches that can work with these data limitations.

B. Correctness of Results vs. Urgency

There is a clear need for rapid results, yet the methods surveyed in this paper are largely based on statistical learning using (rapidly produced) datasets. In a recent systematic review of prediction models for diagnosis and prognosis of COVID-19, Wynants et al. [202] report that all 31 reviewed prediction models have a high risk of bias (due to non-representative selection of control patients and model overfitting). The reported models are therefore susceptible to errors. This is an inherent risk in all scientific work but, given the fast-moving nature of the situation, errors can have severe consequences. It should further be remembered that the outcomes of research may impact healthcare policy. For example, predictions may be used by governments to decide the extent of social distancing. Yet political actors are often less well placed to understand the nuance of scientific studies. We therefore posit that a key challenge is balancing exigency vs. the need for well-evidenced and reproducible results that can inform policy.
Due to the above, another clear challenge is finding ways to capture and represent the uncertainty of conclusions produced within the flurry of research. Bayesian methods can be used to capture uncertainty, although we have seen limited quantification of uncertainty in studies so far [203]. To ensure the correctness of data analysis, researchers must also describe their goals and process, and facilitate reproducible conclusions, e.g., sharing code, data and documentation. This, again, can create challenges as such requirements are balanced against the need for urgency. Another potential avenue is ‘Explainable AI’ [204], which can be used to provide context to results. That said, it is not clear if this will protect against problems such as unintentional bias [205] or even adversarial scenarios [206].

C. Security, Privacy, and Ethics

Most of the works that we discussed imply the sharing and/or use of potentially personal and sensitive data. Devising solutions that exhibit good results but also protect privacy and adhere to high ethical standards is a key challenge. We argue that this could be vital for encouraging uptake among populations, particularly as infrastructure setup may persist beyond the pandemic [207]. There are already substantial efforts to build privacy-preserving medical analytics. For example, MedCo [208] uses homomorphic encryption to allow sites to federate datasets with privacy guarantees. Drynx [209] supports privacy-conscious statistical analysis on distributed datasets. This links closely into the availability of data (see §VI-A), as often data can only be shared when robust privacy guarantees are in place.

Broadly speaking, there is some consensus as outlined in Floridi et al. [210] on the five main “AI ethics principles”: (1) beneficence, (2) non-maleficence, (3) autonomy, (4) justice, and (5) explicability. However, in the situation imposed by COVID-19, decisions may need to choose a tradeoff between these AI ethics virtues [211], [212]. For example, to what extent does the current situation warrants the prioritisation of “public health” and “beneficence” over “individual privacy” and “autonomy”. And even if this is warranted in the short-term, how can we ensure that these compromises do not become permanent and is possible to roll back these tradeoffs in the future as the situation changes. Other difficult questions include the issue of allocation of scarce resources and the tradeoffs involved therein. As highlighted in the Call for Action presented in March 2020 by a coalition of experts on data governance [213], there is also a need for data sharing between the public and private sectors to ensure that data is used for “beneficence”. In effect, the failure to share data in such contexts may be considered maleficence since withholding critical data may block an opportunity to bring potential benefit. That said, good governance mechanisms with suitable regulations should be in place to oversee ethical use of data as much as possible.

Privacy may also become particularly challenging when considering the roll-out of interventions (e.g., targeted social distancing measures), as the intervention itself may expose sensitive information [214]. This, for example, may apply to contact tracing apps, which strive to notify users when they have been in contact with an infected person. Although privacy-preserving implementations exist (e.g., DP-3T, TraceSecure), notifications may still allow users to guess who the infected person is (see [215] for a discussion of security issues in tracing apps).

To move ahead, simple measures can be adopted to help ensure ethical data science research. For example, data collected should be transparent (the users should be informed about what data is being collected) and stewarded with a limited purpose (even when it is anonymised) and governed with ethical oversight and appropriate safeguards (e.g., with time limits and sunset provisions). Interested readers are referred to several comprehensive resources on data ethics [210], [216]–[220], and to a recent report from the TUM Institute for Ethics in Artificial Intelligence [211] and the IEEE Global Initiative on Ethics of Autonomous and Intelligent Systems [212] on the ethical challenges involved in using AI for managing the COVID-19 outbreak.

D. The Need For Multidisciplinary Collaboration

Our understanding of COVID-19’s long-term impact is preliminary. Contributing serious insights will require a mix of domain expertise from multiple fields, and there is already a push for better international collaboration and tracking of COVID-19 [221]. For example, the use of black-box models might yield a superficially practical solution, but could be useless without the involvement of (international) medical and biotechnology expert interpretations. This will further have implications for licensing technologies and engendering uptake (as healthcare professionals are unlikely to engage with technologies developed without medical expertise). Rapidly bringing together cohorts of complementary expertise is therefore important. This also brings many further challenges, e.g., ensuring a team’s interpretation of things like ethics, benefits and risks are coherent.

E. New Data Modalities

The data science community has limited exposure to certain modalities of data that may prove critical in combating COVID-19. A natural challenge is rapidly adapting existing techniques to reflect these new data types. For example, whereas the community has substantial expertise in computer vision tasks, there is less experience in processing ultrasound scans. Yet these have shown good results that are similar to chest CT scans and superior to standard chest radiography for the evaluation of pneumonia and/or acute respiratory distress syndrome (ARDS) in corona patients [222], [223]. They also have the benefit of greater ease of use, absence of radiation, and low cost. Despite these advantages, to the best of our knowledge, no study has yet explored the potential of automatically detecting COVID-19 infections via ultrasound scans. Similarly, magnetic resonance imaging (MRI) is considered the safest imaging modality as it is a non-invasive and non-ionising technique, which provides a high resolution image and excellent soft tissue contrast [102].

Some studies like [224] have described the significance of MRI in fighting against COVID-19 infections. Yet the modality remained under-explored by the computer vision community due to a lack of sufficient training data. Thus, a challenge is to rapidly develop a well-annotated dataset of such medical imaging modalities.
F. Solutions for the Developing World

The COVID-19 pandemic poses unique challenges to populations that have limited access to healthcare (e.g. in developing countries), particularly as such people are disproportionately affected by limited access to information [225]. A key challenge is developing technologies that are designed so that they are globally inclusive. This requires considering how such technologies will impact different communities, and exploring how they could be deployed in both rural and economically deprived regions [226]–[228], as well as how they might be misused in certain contexts. This subsumes several practical challenges that naturally vary based on the specific use case. For example, if building a mobile app for contact tracing, it should be low cost and require limited resources; it should be designed with limited network connectivity in-mind; it should also support multiple languages and be accessible to illiterate users or those with disabilities. We emphasise that ensuring wide accessibility of technological solutions is critical for addressing this global pandemic.

VII. CONCLUSIONS

Data scientists have been active in addressing the emerging challenges related to COVID-19. This paper has been written to rapidly make available a summary of ongoing work for the wider community. We have attempted to make five broad contributions. We first presented relevant use cases of data science, which have the potential to help in the pandemic. This is by no means a comprehensive list and we expect the set to expand in the coming months. We then focused on summarising publicly available datasets for use by researchers. Again, this is intended as a community resource to shorten the time taken to discover relevant data. Following this, we surveyed some of the ongoing research in this area. As the paper is mainly intended for a computer science and engineering audience, we again themed our analysis around the different types of datasets available. Following this, we broadened our analysis and presented a bibliometric study of thousands of publications in recent months. Finally, we highlighted some of the common challenges we observed as part of our systematic review, e.g., availability of data and privacy concerns. We also note that many of the systems discussed in this paper are not operational yet. In view of this, we intend to update the paper repeatedly with new information.
